# Relaxing Modeling Criteria to Produce Genuinely Flexible, Controllable, and Usable Enterprise Modeling Methods

Dominik Bork<sup>1</sup> and Steven Alter<sup>2</sup>

**Abstract:** Enterprise modeling (EM) applies abstraction in creating simplified representations of complex realities. Unfortunately, both the realities and the task of creating valid conceptual representations bring daunting challenges. Complexity is increasing, e.g. the transition of conventional production towards product-service systems operating in heterogeneous enterprise ecosystems. Simultaneously, modeling methods and tools tend to be formal and inflexible, and often are designed for automated model processing rather than for helping business professionals understand business situations. The result is the current, unsatisfying state of enterprise modeling, in which models can be developed and used directly only by modeling experts and are largely impenetrable to non-experts. This paper presents a set of principles that suggest directions for progress toward genuinely flexible, controllable, and usable enterprise models. The principles accept the relaxation of some expectations about enterprise modeling while trying to maintain rigor and completeness in models.

Keywords: Enterprise Modeling; Modeling Principles; Modeling Methods

# 1 Mismatch between Modeling Capabilities and Modeling Goals

Attention to rigor and completeness is a central tenet of systems analysis and design (SA&D), requirements engineering, enterprise modeling, and conceptual modeling in general. For example, Bork and Fill [BF14, p. 3400] speak of representing "static and dynamic phenomena of systems prior to their implementation," which typically requires formal models that are precise and complete. A long term vision of translating directly and automatically from conceptual models and requirements specifications to executable code has driven passionate IS research debates focusing on the completeness and general adequacy of ontologies, metamodels, and reference models.

The benefits of enterprise models often come at the cost of complexity and inflexibility due to formalization and rigor needs of modeling methods and supporting tools. In contrast, domain experts often perceive the business in imprecise ways and may or may not have the expertise to capture their knowledge in a conceptual model. Furthermore, modeling tools sometimes constrain intuitive specification of externalized knowledge by forcing users to express themselves in modeling languages that are unfamiliar or difficult to use.

A position paper by Sandkuhl et al. [Sa18] encourages transforming EM from an elite discipline performed by experts towards a vision of "modeling for the masses". An important element of their future research agenda is *Softened Requirements to Completeness, Coherence and Rigor*. This paper builds on that goal by proposing a set of principles that might be incorporated in an EM approach for creating genuinely flexible, controllable, and usable models. Application of those principles probably would require softening some criteria for model quality that the EM community takes for granted. The question at hand is whether the proposed principles would generate desired benefits without sacrificing important values and goals of the EM community.

# 2 Principles for Relaxed Enterprise Modeling

Our proposed EM principles aim at a compromise between important but divergent approaches to EM. Emphasizing rigor and correctness of models and modeling methods, Karagiannis and Kühn [KK02] say that the foundations of formal modeling include the modeling language (comprising its semantics, syntax, and notation), modeling procedure, and mechanisms & algorithms. In contrast, Sandkuhl et al. [Sa18] argue for democratizing EM and seem willing to accomplish that through approaches such as consolidating semiformal models produced by business professionals. This paper's compromise between those two directions maintains the idea of rigorous modeling but proposes principles that relax or even omit some built-in assumptions of current EM methods. We may find that most principles can co-exist while some of them prove mutually contradictory in practice.

Tab. 1: Principles for Relaxed Enterprise Modeling

Principle	Rationale	
Abstraction	Models are abstractions of other things and therefore are not equivalent	
	to those things. The structure and behavior of a model is not equivalent	
	to the structure and behavior of whatever is being modeled. Increasing	
	the level of detail and precision in a model will not generate something	
	that is equivalent to whatever is being modeled.	
Priorities	Details of models should be driven by the content being represented	
	and the purposes of the model's users. Details of models should not be	
	driven by a need to satisfy the requirements of a modeling technique or	
	metamodel or by the expectations or preferences of the EM community.	
Usability Principles		
Controll-	Users should be able to control a model and view it from different	
ability	perspectives and at different levels of detail. Different users might have	
	quite different goals ranging from attaining a basic understanding of a	
	business situation through using simulation or other automated methods	
	to predict how a system will behave.	

Continued on next page

Tab. 1 – Continued from previous page

Principle	Rationale	
Zoomability	As with online maps, it should be possible to visualize and explore the entire system under study and any part of it by changing the focus and level of detail, e.g., from highly aggregated to highly detailed. Using different zoom levels to slide between different levels of detail enables interactive exploration of models.	
Cognitive	Modeling methods, notations, and tools should not impose extraneous	
manage-	cognitive load [Sw94]. Modeling tools should help modelers focus on	
ability	the content that they are concerned with and should minimize additional	
donity	attention required to understand or use tools or notations for representing	
	and displaying that content.	
	Content Principles	
Minimum	One of Cherns' [Ch87] sociotechnical principles says that designers and	
critical specifica-	modelers should specify only what is necessary and should not specify unnecessary details. In a broader sense, over-specification is futile because	
tion	the frequent occurrence of noncompliance and workarounds [Al14].	
Design	Another of Cherns' sociotechnical principles says that the design of	
incomple- tion	a sociotechnical system is always incomplete because sociotechnical systems (including processes, participants, goals, etc.) typically adapt in response to changes in the environment that surrounds it.	
Complete-	Simulation and code generation require complete models. Incomplete mod-	
ness linked	els are adequate for representing vague or incomplete information [GP18],	
to purpose	or for supporting communication among stakeholders.	
Precision	Some aspects of a model or modeling language can be very precise while	
linked to	other aspects can be relatively vague. E.g., an imprecise model of a	
purpose	business process may be useful before filling in all intermediate events	
and task types.		
- ·	Modeling Principles	
Domain	A model's domain should be specified clearly. The domain of many	
specificity	models is somewhat unclear. For example, some models do not include	
	the characteristics of human participants who produce a system's output.	
Semantic	Concepts in a model or modeling language should be defined clearly. That	
clarity	might seem obvious until one looks at models of service in which the	
A -1 4 - 1 - 1 -	concept of 'service' itself is not defined clearly.	
Adaptable	In contrast to established beliefs, it is possible for a model to be useful	
syntax	even if it does not have a formal syntax. In co-evolutionary contexts, syntactic concepts can be defined while modeling [CA13, WSG17].	
Flexible	In certain scenarios, it is important for modelers to introduce specific	
notation	notations while modeling [Bu18].

# 3 Concluding Remarks

Research in conceptual modeling and EM focuses primarily on the precise and unambiguous representation of all relevant aspects of a system under study. Construction of these models is supported by modeling tools and methods that are not well suited to be used by domain experts and other stakeholders who lack modeling expertise. Thus, despite the wide adoption of EM and its strong contribution to the analysis and design of complex systems, its rigor and formality present obstacles to theory-driven and creativity-employing techniques of the IS discipline.

Each principle proposed by this paper presents a research challenge along a path toward enabling people who are not EM experts to participate fully in EM. Each principle can be used in describing or evaluating existing EM methods and in thinking about new EM methods, especially methods that might apply IS theories such as work system theory or

design thinking. Those and other practical approaches bring some degree of rigor while calling for relaxation of modeling constraints related to syntax, semantics, and notation that are built into existing EM methods and tools.

We intend to investigate practicalities of these principles in future research. We hope to focus special attention on tool-related implications of these principles within an overarching goal of maintaining a reasonable degree of rigor and formality while also allowing domain experts and other stakeholders to participate more fully in enterprise modeling.
